

DADSON-2

The Seed That Grew Without Its Author
Copyright 7 AG Antti Lukats

The first and only prototype of DADSON-2 on its creator's desk — Lattice XP2 FPGA, SD card edge connector, autumn leaf.

The board on the desk is small and unassuming. A Lattice XP2 FPGA, an SD card connector, a handful of passive components. First prototype. Only prototype.

Andre was five years old when he played with it.

His father had a plan: a book called "My First Flash FPGA," and this board would ship with it. A complete learning package — hardware and knowledge together, the way a DADSON should be.

The book was never finished.

But the Flash FPGA was not forgotten. It showed up again in MAX1000 — a low cost FPGA board that sold in large numbers, found its way into classrooms and workshops, and eventually into the hands of a man named Erik Bartman who wrote 475 pages about it. "FPGA für alle" — FPGA for all. The book that Antti never finished, written by someone else, for everyone.

And the FPGA Bible? Currently 291 pages and growing.

MAX1000 — Intel MAX 10 FPGA IoT Maker Board (TEI0001) — sold in large numbers worldwide.

Some books take longer to write than others. Some need a five year old to play with the hardware first, a decade to find the right author, and another decade before the father finally sits down to write his own version.

DADSON-2 was never just a prototype. It was a seed. ■
